This interface allows easy replacement of the factory Bose radio and retains the factory Bose amplifier operation in the vehicle.

Connect a powered, speaker level aftermarket head unit to the pre stripped wires following normal EIA wire colors. **Note that the blue wire of the interface should be connected to the remote output (blue/white) wire of the aftermarket radio. The vehicle has only one turn on wire for both the factory amplifier and antenna. The blue/white wire of the interface is not used.**

Plug into the main audio connector removed from the factory radio into the interface harness. The red wire must be connected to switched ignition source in the vehicle because the factory audio connector does not have a switched ignition source.

The 9-pin connector removed from the factory radio should be plugged to the 9 pin connector on the output of the OEM-1 interface. The pair of RCA connectors on this cable can be used for adding additional amplifiers but this is not necessary for head unit replacement. The blue/white wire is provided as a remote turn on if an additional amplifier is used.

The small 4-pin connector, also removed from the factory radio is not used.
